

For this homework, each scene required identifying what was missing for certain objects, physics, and collision logic. In the first problem, I added two walls so the environment had boundaries that the character was confined to. In the second problem, I enabled physics on the rigid body and added gravity and friction to the crate so that it responded to forces instead of floating or sliding unrealistically. In the third problem, I added gravity to the crates and changed the Godot character's motion mode to grounded instead of floating, which made movement feel more realistic, in a world with gravity. In the last problem, I added a collision shape to the character body, so the character would collide against the floor. I also disabled the collision shape on the tree so that the character could pass through it, correcting how objects interacted spatially. Each fix seemed small, but overall reinforced how much game logic depends on consistent physical and collision systems.

Walton explains that props in games generate fictional truths, and that sometimes make believe is oriented toward the props themselves rather than toward a fully immersive fictional world. In Godot, a crate is only pixels with collision and physics properties. Yet once gravity, friction, and rigid body behavior are enabled, that cluster of pixels becomes fictionally heavy, movable, and resistant. The code does not simply display an image of a crate. It establishes rules that allow the crate to function as a prop within a simulated world. Adding walls, gravity, and collision shapes was not only a technical correction but also a restoration of the world's internal logic. The props become meaningful when they reliably generate the expected outcomes within the game's system.

In Unpacking, cardboard boxes carry the story of a life not through dialogue but through objects placed in space. The player interprets relationships and transitions through where items fit and where they do not. When she moves in with her boyfriend, her belongings are squeezed into limited spaces, making it feel as though she is living at his apartment rather than in a shared home. Her objects never fully integrate with his. By contrast, when she later lives with her girlfriend, their possessions feel more balanced and mutually arranged, suggesting a more harmonious partnership through spatial organization alone. Just as restoring gravity and collision in Godot allowed crates and walls to generate the right physical truths, the spatial rules in Unpacking allow objects to generate emotional and relational truths.
